# SYSTEMS AND METHODS FOR TERRESTRIAL REUSE OF CELLULAR SATELLITE FREQUENCY SPECTRUM IN A TIME-DIVISION DUPLEX MODE

## Cross-Reference to Related Applications

This application claims the benefit of Application Serial No. 10/074,097, filed February 12, 2002, entitled *Systems and Methods for Terrestrial Reuse of Cellular Satellite Frequency Spectrum*, which itself claims the benefit of provisional Application No. 60/322,240, filed September 14, 2001, entitled *Systems and Methods for Terrestrial Re-Use of Mobile Satellite Spectrum*, both of which are assigned to the assignee of the present application, the disclosures of both of which are hereby incorporated herein by reference in their entirety as if set forth fully herein.

## Field of the Invention

This invention relates to radiotelephone communications systems and methods, and more particularly to terrestrial cellular and satellite cellular radiotelephone communications systems and methods.

## Background of the Invention

Satellite radiotelephone communications systems and methods are widely used for radiotelephone communications. Satellite radiotelephone communications systems and methods generally employ at least one space-based component, such as one or more satellites that are configured to wirelessly communicate with a plurality of satellite radiotelephones.

A satellite radiotelephone communications system or method may utilize a single antenna beam covering an entire area served by the system. Alternatively, in cellular satellite radiotelephone communications systems and methods, multiple beams are provided, each of which can serve distinct geographical areas in the overall service region, to collectively serve an overall satellite footprint. Thus, a cellular architecture similar to that used in conventional terrestrial cellular radiotelephone systems and methods can be implemented in cellular satellite-based systems and

methods. The satellite typically communicates with radiotelephones over a bidirectional communications pathway, with radiotelephone communication signals being communicated from the satellite to the radiotelephone over a downlink or forward link, and from the radiotelephone to the satellite over an uplink or return link.

The overall design and operation of cellular satellite radiotelephone systems and methods are well known to those having skill in the art, and need not be described further herein. Moreover, as used herein, the term "radiotelephone" includes cellular and/or satellite radiotelephones with or without a multi-line display; Personal Communications System (PCS) terminals that may combine a radiotelephone with data processing, facsimile and/or data communications capabilities; Personal Digital Assistants (PDA) that can include a radio frequency transceiver and a pager, Internet/intranet access, Web browser, organizer, calendar and/or a global positioning system (GPS) receiver; and/or conventional laptop and/or palmtop computers or other appliances, which include a radio frequency transceiver.

Terrestrial networks can enhance cellular satellite radiotelephone system availability, efficiency and/or economic viability by terrestrially reusing at least some of the frequency bands that are allocated to cellular satellite radiotelephone systems. In particular, it is known that it may be difficult for cellular satellite radiotelephone systems to reliably serve densely populated areas, because the satellite signal may be blocked by high-rise structures and/or may not penetrate into buildings. As a result, the satellite spectrum may be underutilized or unutilized in such areas. The use of terrestrial retransmission can reduce or eliminate this problem.

Moreover, the capacity of the overall system can be increased significantly by the introduction of terrestrial retransmission, since terrestrial frequency reuse can be much denser than that of a satellite-only system. In fact, capacity can be enhanced where it may be mostly needed, i.e., densely populated urban/industrial/commercial areas. As a result, the overall system can become much more economically viable, as it may be able to serve a much larger subscriber base. Finally, satellite radiotelephones for a satellite radiotelephone system having a terrestrial component within the same satellite frequency band and using substantially the same air interface for both terrestrial and satellite communications can be more cost effective and/or aesthetically appealing. Conventional dual band/dual mode alternatives, such as the well known Thuraya, Iridium and/or Globalstar dual mode satellite/terrestrial

radiotelephone systems, may duplicate some components, which may lead to increased cost, size and/or weight of the radiotelephone.

One example of terrestrial reuse of satellite frequencies is described in U.S. Patent 5,937,332 to the present inventor Karabinis entitled *Satellite Telecommunications Repeaters and Retransmission Methods*, the disclosure of which is hereby incorporated herein by reference in its entirety as if set forth fully herein. As described therein, satellite telecommunications repeaters are provided which receive, amplify, and locally retransmit the downlink signal received from a satellite thereby increasing the effective downlink margin in the vicinity of the satellite telecommunications repeaters and allowing an increase in the penetration of uplink and downlink signals into buildings, foliage, transportation vehicles, and other objects which can reduce link margin. Both portable and non-portable repeaters are provided. See the abstract of U.S. Patent 5,937,332.

In view of the above discussion, there continues to be a need for systems and methods for terrestrial reuse of cellular satellite frequencies that can allow improved reliability, capacity, cost effectiveness and/or aesthetic appeal for cellular satellite radiotelephone systems, methods and/or satellite radiotelephones.

## Summary of the Invention

Some embodiments of the present invention allow a satellite radiotelephone frequency to be reused terrestrially within the same satellite cell in time-division duplex mode. In particular, some embodiments of the present invention include a space-based component, such as a satellite, that is configured to receive wireless communications from radiotelephones in a satellite footprint over an uplink satellite radiotelephone frequency, and to transmit wireless communications to the radiotelephones over a downlink radiotelephone frequency. An ancillary terrestrial network, comprising one or more ancillary terrestrial components, is configured to transmit wireless communications to, and receive wireless communications from, the radiotelephones over the downlink satellite radiotelephone frequency in a time-division duplex mode. By terrestrially transmitting and receiving wireless communications over the downlink satellite radiotelephone frequency in a time-division duplex mode, interference at the space-based component, by the ancillary terrestrial network and/or the radiotelephones due to terrestrial reuse of cellular satellite frequency spectrum, may be reduced or eliminated.

In other embodiments of the present invention, the ancillary terrestrial network also is configured to transmit wireless communications to, and receive wireless communications from, the radiotelephones over the uplink satellite radiotelephone frequency in a time-division duplex mode. In yet other embodiments, the space-based component may be configured to receive wireless communications from the radiotelephones and to transmit wireless communications to the radiotelephones over the uplink satellite radiotelephone frequency and/or the downlink satellite radiotelephone frequency in a time-division duplex mode.

In some embodiments of the present invention, the time-division duplex mode includes a frame including a plurality of slots. At least a first one of the slots is used to transmit wireless communications to the radiotelephones over the downlink satellite radiotelephone frequency. At least a second one of the slots is used to receive wireless communications from the radiotelephones over the downlink satellite radiotelephone frequency.

In still other embodiments, the downlink satellite radiotelephone frequency comprises a downlink satellite radiotelephone frequency band. The ancillary terrestrial network is configured to transmit wireless communications to, and receive wireless communications from, the radiotelephone over the downlink satellite radiotelephone frequency band in a time-division duplex mode.

In yet other embodiments of the present invention, the time-division duplex mode employs a frame including a plurality of slots. A first number of the slots is used to transmit wireless communications to the radiotelephones over the downlink satellite radiotelephone frequency. A second number of the slots is used to receive wireless communications from the radiotelephones over the downlink satellite radiotelephone frequency. In some embodiments, the first number is greater than the second number.

In still other embodiments, at least a first one of the slots is used to transmit wireless communications to the radiotelephones over the downlink satellite radiotelephone frequency a first modulation and/or protocol such as EDGE modulation and/or protocol. At least a second one of the slots is used to receive wireless communications from the radiotelephones over the downlink satellite radiotelephone frequency using a second modulation and/or protocol, such as GPRS modulation and/or protocol, that is less spectrally efficient than the first modulation and/or protocol.

It will be understood by those having skill in the art that the above embodiments have been described primarily with respect to a satellite radiotelephone system that includes a space-based component and an ancillary terrestrial network. However, other embodiments of the invention can provide an ancillary terrestrial component, a radiotelephone and/or satellite radiotelephone communication methods for the space-based component, the ancillary terrestrial network and/or the radiotelephones. Accordingly, a downlink satellite radiotelephone frequency or frequencies can be reused terrestrially in a time-division duplex mode while reducing, minimizing or eliminating interference with space-based use of the downlink satellite radiotelephone frequency or frequencies.

## Brief Description of the Drawings

Figure 1 is a schematic diagram of cellular radiotelephone systems and methods according to embodiments of the invention.

Figure 2 is a block diagram of adaptive interference reducers according to embodiments of the present invention.

Figure 3 is a spectrum diagram that illustrates satellite L-band frequency allocations.

Figure 4 is a schematic diagram of cellular satellite systems and methods according to other embodiments of the present invention.

Figure 5 illustrates time-division duplex frame structures according to embodiments of the present invention.

Figure 6 is a block diagram of architectures of ancillary terrestrial components according to embodiments of the invention.

Figure 7 is a block diagram of architectures of reconfigurable radiotelephones according to embodiments of the invention.

Figure 8 graphically illustrates mapping of monotonically decreasing power levels to frequencies according to embodiments of the present invention.

Figure 9 illustrates an ideal cell that is mapped to three power regions and three associated carrier frequencies according to embodiments of the invention.

Figure 10 depicts a realistic cell that is mapped to three power regions and three associated carrier frequencies according to embodiments of the invention.

Figure 11 illustrates two or more contiguous slots in a frame that are unoccupied according to embodiments of the present invention.

Figure 12 illustrates loading of two or more contiguous slots with lower power transmissions according to embodiments of the present invention.

## Detailed Description

The present invention now will be described more fully hereinafter with reference to the accompanying drawings, in which typical embodiments of the invention are shown. This invention may, however, be embodied in many different forms and should not be construed as limited to the embodiments set forth herein. Rather, these embodiments are provided so that this disclosure will be thorough and complete, and will fully convey the scope of the invention to those skilled in the art. Like numbers refer to like elements throughout.

Figure 1 is a schematic diagram of cellular satellite radiotelephone systems and methods according to embodiments of the invention. As shown in Figure 1, these cellular satellite radiotelephone systems and methods **100** include at least one Space-Based Component (SBC) **110**, such as a satellite. The space-based component **110** is configured to transmit wireless communications to a plurality of radiotelephones **120a**, **120b** in a satellite footprint comprising one or more satellite radiotelephone cells **130-130''''** over one or more satellite radiotelephone forward link (downlink) frequencies $f_D$. The space-based component **110** is configured to receive wireless communications from, for example, a first radiotelephone **120a** in the satellite radiotelephone cell **130** over a satellite radiotelephone return link (uplink) frequency $f_U$. An ancillary terrestrial network, comprising at least one ancillary terrestrial component **140**, which may include an antenna **140a** and an electronics system **140b** (for example, at least one antenna **140a** and at least one electronics system **140b**), is configured to receive wireless communications from, for example, a second radiotelephone **120b** in the radiotelephone cell **130** over the satellite radiotelephone uplink frequency, denoted $f'_U$, which may be the same as $f_U$. Thus, as illustrated in Figure 1, radiotelephone **120a** may be communicating with the space-based component **110** while radiotelephone **120b** may be communicating with the ancillary terrestrial component **140**. As shown in Figure 1, the space-based component **110** also undesirably receives the wireless communications from the second radiotelephone **120b** in the satellite radiotelephone cell **130** over the satellite

radiotelephone frequency $f'_U$ as interference. More specifically, a potential interference path is shown at **150**. In this potential interference path **150**, the return link signal of the second radiotelephone **120b** at carrier frequency $f'_U$ interferes with satellite communications. This interference would generally be strongest when $f'_U = f_U$, because, in that case, the same return link frequency would be used for space-based component and ancillary terrestrial component communications over the same satellite radiotelephone cell, and no spatial discrimination between satellite radiotelephone cells would appear to exist.

Still referring to Figure 1, embodiments of satellite radiotelephone systems/methods **100** can include at least one gateway **160** that can include an antenna **160a** and an electronics system **160b** that can be connected to other networks **162** including terrestrial and/or other radiotelephone networks. The gateway **160** also communicates with the space-based component **110** over a satellite feeder link **112**. The gateway **160** also communicates with the ancillary terrestrial component **140**, generally over a terrestrial link **142**.

Still referring to Figure 1, an Interference Reducer (IR) **170a** also may be provided at least partially in the ancillary terrestrial component electronics system **140b**. Alternatively or additionally, an interference reducer **170b** may be provided at least partially in the gateway electronics system **160b**. In yet other alternatives, the interference reducer may be provided at least partially in other components of the cellular satellite system/method **100** instead of or in addition to the interference reducer **170a** and/or **170b**. The interference reducer is responsive to the space-based component **110** and to the ancillary terrestrial component **140**, and is configured to reduce the interference from the wireless communications that are received by the space-based component **110** and is at least partially generated by the second radiotelephone **120b** in the satellite radiotelephone cell **130** over the satellite radiotelephone frequency $f'_U$. The interference reducer **170a** and/or **170b** uses the wireless communications $f'_U$ that are intended for the ancillary terrestrial component **140** from the second radiotelephone **120b** in the satellite radiotelephone cell **130** using the satellite radiotelephone frequency $f'_U$ to communicate with the ancillary terrestrial component **140**.

In embodiments of the invention, as shown in Figure 1, the ancillary terrestrial component **140** generally is closer to the first and second radiotelephones **120a** and **120b**, respectively, than is the space-based component **110**, such that the wireless

communications from the second radiotelephone **120b** are received by the ancillary terrestrial component **140** prior to being received by the space-based component **110**. The interference reducer **170a** and/or **170b** is configured to generate an interference cancellation signal comprising, for example, at least one delayed replica of the wireless communications from the second radiotelephone **120b** that are received by the ancillary terrestrial component **140**, and to subtract the delayed replica of the wireless communications from the second radiotelephone **120b** that are received by the ancillary terrestrial component **140** from the wireless communications that are received from the space-based component **110**. The interference reduction signal may be transmitted from the ancillary terrestrial component **140** to the gateway **160** over link **142** and/or using other conventional techniques.

Thus, adaptive interference reduction techniques may be used to at least partially cancel the interfering signal, so that the same, or other nearby, satellite radiotelephone uplink frequency can be used in a given cell for communications by radiotelephones **120** with the satellite **110** and with the ancillary terrestrial component **140**. Accordingly, all frequencies that are assigned to a given cell **130** may be used for both radiotelephone **120** communications with the space-based component **110** and with the ancillary terrestrial component **140**. Conventional systems may avoid terrestrial reuse of frequencies within a given satellite cell that are being used within the satellite cell for satellite communications. Stated differently, conventionally, only frequencies used by other satellite cells may be candidates for terrestrial reuse within a given satellite cell. Beam-to-beam spatial isolation that is provided by the satellite system was relied upon to reduce or minimize the level of interference from the terrestrial operations into the satellite operations. In sharp contrast, embodiments of the invention can use an interference reducer to allow all frequencies assigned to a satellite cell to be used terrestrially and for satellite radiotelephone communications.

Embodiments of the invention according to Figure 1 may arise from a realization that the return link signal from the second radiotelephone **120b** at $f_U$ generally will be received and processed by the ancillary terrestrial component **140** much earlier relative to the time when it will arrive at the satellite gateway **160** from the space-based component **110** via the interference path **150**. Accordingly, the interference signal at the satellite gateway **160b** can be at least partially canceled. Thus, as shown in Figure 1, an interference cancellation signal, such as the demodulated ancillary terrestrial component signal, can be sent to the satellite

gateway **160b** by the interference reducer **170a** in the ancillary terrestrial component **140**, for example using link **142**. In the interference reducer **170b** at the gateway **160b**, a weighted (in amplitude and/or phase) replica of the signal may be formed using, for example, adaptive transversal filter techniques that are well known to those having skill in the art. Then, a transversal filter output signal is subtracted from the aggregate received satellite signal at frequency $f'_U$ that contains desired as well as interference signals. Thus, the interference cancellation need not degrade the signal-to-noise ratio of the desired signal at the gateway **160**, because a regenerated (noise-free) terrestrial signal, for example as regenerated by the ancillary terrestrial component **140**, can be used to perform interference suppression.

Figure 2 is a block diagram of embodiments of adaptive interference cancellers that may be located in the ancillary terrestrial component **140**, in the gateway **160**, and/or in another component of the cellular radiotelephone system **100**. As shown in Figure 2, one or more control algorithms **204**, known to those having skill in the art, may be used to adaptively adjust the coefficients of a plurality of transversal filters **202a-202m**. Adaptive algorithms, such as Least Mean Square Error (LMSE), Kalman, Fast Kalman, Zero Forcing and/or various combinations thereof or other techniques may be used. It will be understood by those having skill in the art that the architecture of Figure 2 may be used with an LMSE algorithm. However, it also will be understood by those having skill in the art that conventional architectural modifications may be made to facilitate other control algorithms.

Additional embodiments of the invention now will be described with reference to Figure 3, which illustrates L-band frequency allocations including cellular radiotelephone system forward links and return links. As shown in Figure 3, the space-to-ground L-band forward link (downlink) frequencies are assigned from 1525 MHz to 1559 MHz. The ground-to-space L-band return link (uplink) frequencies occupy the band from 1626.5 MHz to 1660.5 MHz. Between the forward and return L-band links lie the GPS/GLONASS radionavigation band (from 1559 MHz to 1605 MHz).

In the detailed description to follow, GPS/GLONASS will be referred to simply as GPS for the sake of brevity. Moreover, the acronyms ATC and SBC will be used for the ancillary terrestrial component and the space-based component, respectively, for the sake of brevity.

As is known to those skilled in the art, GPS receivers may be extremely sensitive since they are designed to operate on very weak spread-spectrum radionavigation signals that arrive on the earth from a GPS satellite constellation. As a result, GPS receivers may to be highly susceptible to in-band interference. ATCs that are configured to radiate L-band frequencies in the forward satellite band (1525 to 1559 MHz) can be designed with very sharp out-of-band emissions filters to satisfy the stringent out-of-band spurious emissions desires of GPS.

Referring again to Figure 1, some embodiments of the invention can provide systems and methods that can allow an ATC **140** to configure itself in one of at least two modes. In accordance with a first mode, which may be a standard mode and may provide highest capacity, the ATC **140** transmits to the radiotelephones **120** over the frequency range from 1525 MHz to 1559 MHz, and receives transmissions from the radiotelephones **120** in the frequency range from 1626.5 MHz to 1660.5 MHz, as illustrated in Figure 3. In contrast, in a second mode of operation, the ATC **140** transmits wireless communications to the radiotelephones **120** over a modified range of satellite band forward link (downlink) frequencies. The modified range of satellite band forward link frequencies may be selected to reduce, compared to the unmodified range of satellite band forward link frequencies, interference with wireless receivers such as GPS receivers that operate outside the range of satellite band forward link frequencies.

Many modified ranges of satellite band forward link frequencies may be provided according to embodiments of the present invention. In some embodiments, the modified range of satellite band forward link frequencies can be limited to a subset of the original range of satellite band forward link frequencies, so as to provide a guard band of unused satellite band forward link frequencies. In other embodiments, all of the satellite band forward link frequencies are used, but the wireless communications to the radiotelephones are modified in a manner to reduce interference with wireless receivers that operate outside the range of satellite band forward link frequencies. Combinations and subcombinations of these and/or other techniques also may be used, as will be described below.

It also will be understood that embodiments of the invention that will now be described in connection with Figures 4-12 will be described in terms of multiple mode ATCs **140** that can operate in a first standard mode using the standard forward and return links of Figure 3, and in a second or alternate mode that uses a modified range

of satellite band forward link frequencies and/or a modified range of satellite band return link frequencies. These multiple mode ATCs can operate in the second, non-standard mode, as long as desirable, and can be switched to standard mode otherwise. However, other embodiments of the present invention need not provide multiple mode ATCs but, rather, can provide ATCs that operate using the modified range of satellite band forward link and/or return link frequencies.

Embodiments of the invention now will be described, wherein an ATC operates with an SBC that is configured to receive wireless communications from radiotelephones over a first range of satellite band return link frequencies and to transmit wireless communications to the radiotelephones over a second range of satellite band forward link frequencies that is spaced apart from the first range. According to these embodiments, the ATC is configured to use at least one time-division duplex frequency to transmit wireless communications to the radiotelephones and to receive wireless communications from the radiotelephones at different times. In particular, in some embodiments, the at least one time-division duplex frequency that is used to transmit wireless communications to the radiotelephones and to receive wireless communications from the radiotelephones at different times, comprises a frame including a plurality of slots. At least a first one of the slots is used to transmit wireless communications to the radiotelephones and at least a second one of the slots is used to receive wireless communications from the radiotelephones. Thus, in some embodiments, the ATC transmits and receives, in Time-division Duplex (TDD) mode, using frequencies from 1626.5 MHz to 1660.5 MHz. In some embodiments, all ATCs across the entire network may have the stated configuration/reconfiguration flexibility. In other embodiments, only some ATCs may be reconfigurable.

Figure 4 illustrates satellite systems and methods **400** according to some embodiments of the invention, including an ATC **140** communicating with a radiotelephone **120b** using a carrier frequency $f''_U$ in TDD mode. Figure 5 illustrates an embodiment of a TDD frame structure. Assuming full-rate GSM (eight time slots per frame), up to four full-duplex voice circuits can be supported by one TDD carrier. As shown in Figure 5, the ATC **140** transmits to the radiotelephone **120b** over, for example, time slot number 0. The radiotelephone **120b** receives and replies back to the ATC **140** over, for example, time slot number 4. Time slots number 1 and 5 may be used to establish communications with another radiotelephone, and so on.

A Broadcast Control CHannel (BCCH) is preferably transmitted from the ATC **140** in standard mode, using a carrier frequency from below any guard band exclusion region. In other embodiments, a BCCH also can be defined using a TDD carrier. In any of these embodiments, radiotelephones in idle mode can, per established GSM methodology, monitor the BCCH and receive system-level and paging information. When a radiotelephone is paged, the system decides what type of resource to allocate to the radiotelephone in order to establish the communications link. Whatever type of resource is allocated for the radiotelephone communications channel (TDD mode or standard mode), the information is communicated to the radiotelephone, for example as part of the call initialization routine, and the radiotelephone configures itself appropriately.

It may be difficult for the TDD mode to co-exist with the standard mode over the same ATC, due, for example, to the ATC receiver LNA stage. In particular, assuming a mixture of standard and TDD mode GSM carriers over the same ATC, during the part of the frame when the TDD carriers are used to serve the forward link (when the ATC is transmitting TDD) enough energy may leak into the receiver front end of the same ATC to desensitize its LNA stage.

Techniques can be used to suppress the transmitted ATC energy over the 1600 MHz portion of the band from desensitizing the ATC's receiver LNA, and thereby allow mixed standard mode and TDD frames. For example, isolation between outbound and inbound ATC front ends and/or antenna system return loss may be increased or maximized. A switchable band-reject filter may be placed in front of the LNA stage. This filter would be switched in the receiver chain (prior to the LNA) during the part of the frame when the ATC is transmitting TDD, and switched out during the rest of the time. An adaptive interference canceller can be configured at RF (prior to the LNA stage). If such techniques are used, suppression of the order of 70 dB can be attained, which may allow mixed standard mode and TDD frames. However, the ATC complexity and/or cost may increase.

Thus, even though ATC LNA desensitization may be reduced or eliminated, it may use significant special engineering and attention and may not be economically worth the effort. Other embodiments, therefore, may keep TDD ATCs pure TDD, with the exception, perhaps, of the BCCH carrier which may not be used for traffic but only for broadcasting over the first part of the frame, consistent with TDD protocol. Moreover, Random Access CHannel (RACH) bursts may be timed so that

they arrive at the ATC during the second half of the TDD frame. In some embodiments, all TDD ATCs may be equipped to enable reconfiguration in response to a command.

It is well recognized that during data communications or other applications, the forward link may use transmissions at higher rates than the return link. For example, in web browsing with a radiotelephone, mouse clicks and/or other user selections typically are transmitted from the radiotelephone to the system. The system, however, in response to a user selection, may have to send large data files to the radiotelephone. Hence, other embodiments of the invention may be configured to enable use of an increased or maximum number of time slots per forward GSM carrier frame, to provide a higher downlink data rate to the radiotelephones.

Thus, when a carrier frequency is configured to provide service in TDD mode, a decision may be made as to how many slots will be allocated to serving the forward link, and how many will be dedicated to the return link. Whatever the decision is, it may be desirable that it be adhered to by all TDD carriers used by the ATC, in order to reduce or avoid the LNA desensitization problem described earlier. In voice communications, the partition between forward and return link slots may be made in the middle of the frame as voice activity typically is statistically bidirectionally symmetrical. Hence, driven by voice, the center of the frame may be where the TDD partition is drawn.

To increase or maximize forward link throughput in data mode, data mode TDD carriers according to embodiments of the invention may use a more spectrally efficient modulation and/or protocol, such as the EDGE modulation and/or protocol, on the forward link slots. The return link slots may be based on a less spectrally efficient modulation and/or protocol such as the GPRS (GMSK) modulation and/or protocol. The EDGE modulation/protocol and the GPRS modulation/protocol are well known to those having skill in the art, and need not be described further herein. Given an EDGE forward/GPRS return TDD carrier strategy, up to $(384/2) = 192$ kbps may be supported on the forward link while on the return link the radiotelephone may transmit at up to $(115/2) \approx 64$ kbps.

In other embodiments, it also is possible to allocate six time slots of an eight-slot frame for the forward link and only two for the return link. In these embodiments, for voice services, given the statistically symmetric nature of voice, the

return link vocoder may need to be comparable with quarter-rate GSM, while the forward link vocoder can operate at full-rate GSM, to yield six full-duplex voice circuits per GSM TDD-mode carrier (a voice capacity penalty of 25%). Subject to this non-symmetrical partitioning strategy, data rates of up to (384)(6/8) = 288 kbps may be achieved on the forward link, with up to (115)(2/8) ≈ 32 kbps on the return link.

Figure 6 depicts an ATC architecture according to embodiments of the invention, which can lend itself to automatic configuration between the two modes of standard GSM and TDD GSM on command, for example, from a Network Operations Center (NOC) via a Base Station Controller (BSC). It will be understood that in these embodiments, an antenna **620** can correspond to the antenna **140a** of Figures 1 and 4, and the remainder of Figure 6 can correspond to the electronics system **140b** of Figures 1 and 4. If a reconfiguration command for a particular carrier, or set of carriers, occurs while the carrier(s) are active and are supporting traffic, then, via the in-band signaling Fast Associated Control CHannel (FACCH), all affected radiotelephones may be notified to also reconfigure themselves and/or switch over to new resources. If carrier(s) are reconfigured from TDD mode to standard mode, automatic reassignment of the carrier(s) to the appropriate standard-mode ATCs, based, for example, on capacity demand and/or reuse pattern can be initiated by the NOC. If, on the other hand, carrier(s) are reconfigured from standard mode to TDD mode, automatic reassignment to the appropriate TDD-mode ATCs can take place on command from the NOC.

Still referring to Figure 6, a switch **610** may remain closed when carriers are to be demodulated in the standard mode. In TDD mode, this switch **610** may be open during the first half of the frame, when the ATC is transmitting, and closed during the second half of the frame, when the ATC is receiving. Other embodiments also may be provided.

Figure 6 assumes N transceivers per ATC sector, where N can be as small as one, since a minimum of one carrier per sector generally is desired. Each transceiver is assumed to operate over one GSM carrier pair (when in standard mode) and can thus support up to eight full-duplex voice circuits, neglecting BCCH channel overhead. Moreover, a standard GSM carrier pair can support sixteen full-duplex voice circuits when in half-rate GSM mode, and up to thirty two full-duplex voice circuits when in quarter-rate GSM mode.

When in TDD mode, the number of full duplex voice circuits may be reduced by a factor of two, assuming the same vocoder. However, in TDD mode, voice service can be offered via the half-rate GSM vocoder with almost imperceptible quality degradation, in order to maintain invariant voice capacity. Figure 7 is a block diagram of a reconfigurable radiotelephone architecture that can communicate with a reconfigurable ATC architecture of Figure 6. In Figure 7, an antenna **720** is provided, and the remainder of Figure 7 can provide embodiments of an electronics system for the radiotelephone.

It will be understood that the ability to reconfigure ATCs and radiotelephones according to embodiments of the invention may be obtained at a relatively small increase in cost. The cost may be mostly in Non-Recurring Engineering (NRE) cost to develop software. Some recurring cost may also be incurred, however, in that at least an additional RF filter and a few electronically controlled switches may be used per ATC and radiotelephone. All other hardware/software can be common to standard-mode and TDD-mode GSM.

Referring now to Figure 8, other radiotelephone systems and methods according to embodiments of the invention now will be described. In these embodiments, the modified second range of satellite band forward link frequencies includes a plurality of frequencies in the second range of satellite band forward link frequencies that are transmitted by the ATCs to the radiotelephones at a power level, such as maximum power level, that monotonically decreases as a function of (increasing) frequency. More specifically, as will be described below, in some embodiments, the modified second range of satellite band forward link frequencies includes a subset of frequencies proximate to a first or second end of the range of satellite band forward link frequencies that are transmitted by the ATC to the radiotelephones at a power level, such as a maximum power level, that monotonically decreases toward the first or second end of the second range of satellite band forward link frequencies. In still other embodiments, the first range of satellite band return link frequencies is contained in an L-band of satellite frequencies above GPS frequencies and the second range of satellite band forward link frequencies is contained in the L-band of satellite frequencies below the GPS frequencies. The modified second range of satellite band forward link frequencies includes a subset of frequencies proximate to an end of the second range of satellite band forward link frequencies adjacent the GPS frequencies that are transmitted by the ATC to the

radiotelephones at a power level, such as a maximum power level, that monotonically decreases toward the end of the second range of satellite band forward link frequencies adjacent the GPS frequencies.

Without being bound by any theory of operation, a theoretical discussion of the mapping of ATC maximum power levels to carrier frequencies according to embodiments of the present invention now will be described. Referring to Figure 8, let $\nu = \mathcal{F}(\rho)$ represent a mapping from the power ($\rho$) domain to the frequency ($\nu$) range. The power ($\rho$) is the power that an ATC uses or should transmit in order to reliably communicate with a given radiotelephone. This power may depend on many factors such as the radiotelephone's distance from the ATC, the blockage between the radiotelephone and the ATC, the level of multipath fading in the channel, etc., and as a result, will, in general, change as a function of time. Hence, the power used generally is determined adaptively (iteratively) via closed-loop power control, between the radiotelephone and ATC.

The frequency ($\nu$) is the satellite carrier frequency that the ATC uses to communicate with the radiotelephone. According to embodiments of the invention, the mapping $\mathcal{F}$ is a monotonically decreasing function of the independent variable $\rho$. Consequently, in some embodiments, as the maximum ATC power increases, the carrier frequency that the ATC uses to establish and/or maintain the communications link decreases. Figure 8 illustrates an embodiment of a piece-wise continuous monotonically decreasing (stair-case) function. Other monotonic functions may be used, including linear and/or nonlinear, constant and/or variable decreases. FACCH or Slow Associated Control CHannel (SACCH) messaging may be used in embodiments of the invention to facilitate the mapping adaptively and in substantially real time.

Figure 9 depicts an ideal cell according to embodiments of the invention, where, for illustration purposes, three power regions and three associated carrier frequencies (or carrier frequency sets) are being used to partition a cell. For simplicity, one ATC transmitter at the center of the idealized cell is assumed with no sectorization. In embodiments of Figure 9, the frequency (or frequency set) $f_I$ is taken from substantially the upper-most portion of the L-band forward link frequency set, for example from substantially close to 1559 MHz (see Figure 3). Correspondingly,

the frequency (or frequency set) $f_M$ is taken from substantially the central portion of the L-band forward link frequency set (see Figure 3). In concert with the above, the frequency (or frequency set) $f_O$ is taken from substantially the lowest portion of the L-band forward link frequencies, for example close to 1525 MHz (see Figure 3).

Thus, according to embodiments of Figure 9, if a radiotelephone is being served within the outer-most ring of the cell, that radiotelephone is being served via frequency $f_O$. This radiotelephone, being within the furthest area from the ATC, has (presumably) requested maximum (or near maximum) power output from the ATC. In response to the maximum (or near maximum) output power request, the ATC uses its a priori knowledge of power-to-frequency mapping, such as a three-step staircase function of Figure 9. Thus, the ATC serves the radiotelephone with a low-value frequency taken from the lowest portion of the mobile L-band forward link frequency set, for example, from as close to 1525 MHz as possible. This, then, can provide additional safeguard to any GPS receiver unit that may be in the vicinity of the ATC.

Embodiments of Figure 9 may be regarded as idealized because they associate concentric ring areas with carrier frequencies (or carrier frequency sets) used by an ATC to serve its area. In reality, concentric ring areas generally will not be the case. For example, a radiotelephone can be close to the ATC that is serving it, but with significant blockage between the radiotelephone and the ATC due to a building. This radiotelephone, even though relatively close to the ATC, may also request maximum (or near maximum) output power from the ATC. With this in mind, Figure 10 may depict a more realistic set of area contours that may be associated with the frequencies being used by the ATC to serve its territory, according to embodiments of the invention. The frequency (or frequency set) $f_I$ may be reused in the immediately adjacent ATC cells owing to the limited geographical span associated with $f_I$ relative to the distance between cell centers. This may also hold for $f_M$.

Referring now to Figure 11, other modified second ranges of satellite band forward link frequencies that can be used by ATCs according to embodiments of the present invention now will be described. In these embodiments, at least one frequency in the modified second range of satellite band forward link frequencies that is transmitted by the ATC to the radiotelephones comprises a frame including a plurality of slots. In these embodiments, at least two contiguous slots in the frame that is transmitted by the ATC to the radiotelephones are left unoccupied. In other embodiments, three contiguous slots in the frame that is transmitted by the ATC to the

radiotelephones are left unoccupied. In yet other embodiments, at least two contiguous slots in the frame that is transmitted by the ATC to the radiotelephones are transmitted at lower power than remaining slots in the frame. In still other embodiments, three contiguous slots in the frame that is transmitted by the ATC to the radiotelephones are transmitted at lower power than remaining slots in the frame. In yet other embodiments, the lower power slots may be used with first selected ones of the radiotelephones that are relatively close to the ATC and/or are experiencing relatively small signal blockage, and the remaining slots are transmitted at higher power to second selected ones of the radiotelephones that are relatively far from the ATC and/or are experiencing relatively high signal blockage.

Stated differently, in accordance with some embodiments of the invention, only a portion of the TDMA frame is utilized. For example, only the first four (or last four, or any contiguous four) time slots of a full-rate GSM frame are used to support traffic. The remaining slots are left unoccupied (empty). In these embodiments, capacity may be lost. However, as has been described previously, for voice services, half-rate and even quarter-rate GSM may be invoked to gain capacity back, with some potential degradation in voice quality. The slots that are not utilized preferably are contiguous, such as slots 0 through 3 or 4 through 7 (or 2 through 5, etc.). The use of non-contiguous slots such as 0, 2, 4, and 6, for example, may be less desirable. Figure 11 illustrates four slots (4-7) being used and four contiguous slots (0-3) being empty in a GSM frame.

It has been found experimentally, according to these embodiments of the invention, that GPS receivers can perform significantly better when the interval between interference bursts is increased or maximized. Without being bound by any theory of operation, this effect may be due to the relationship between the code repetition period of the GPS C/A code (1 msec.) and the GSM burst duration (about 0.577 msec.). With a GSM frame occupancy comprising alternate slots, each GPS signal code period can experience at least one "hit", whereas a GSM frame occupancy comprising four to five contiguous slots allows the GPS receiver to derive sufficient clean information so as to "flywheel" through the error events.

According to other embodiments of the invention, embodiments of Figures 8-10 can be combined with embodiments of Figure 11. Furthermore, according to other embodiments of the invention, if an $f_I$ carrier of Figures 9 or 10 is underutilized,

because of the relatively small footprint of the inner-most region of the cell, it may be used to support additional traffic over the much larger outermost region of the cell.

Thus, for example, assume that only the first four slots in each frame of $f_I$ are being used for inner region traffic. In embodiments of Figures 8-10, these four $f_I$ slots are carrying relatively low power bursts, for example of the order of 100 mW or less, and may, therefore, appear as (almost) unoccupied from an interference point of view. Loading the remaining four (contiguous) time slots of $f_I$ with relatively high-power bursts may have negligible effect on a GPS receiver because the GPS receiver would continue to operate reliably based on the benign contiguous time interval occupied by the four low-power GSM bursts. Figure 12 illustrates embodiments of a frame at carrier $f_I$ supporting four low-power (inner interval) users and four high-power (outer interval) users. In fact, embodiments illustrated in Figure 12 may be a preferred strategy for the set of available carrier frequencies that are closest to the GPS band. These embodiments may avoid undue capacity loss by more fully loading the carrier frequencies.

The experimental finding that interference from GSM carriers can be relatively benign to GPS receivers provided that no more than, for example, 5 slots per 8 slot GSM frame are used in a contiguous fashion can be very useful. It can be particularly useful since this experimental finding may hold even when the GSM carrier frequency is brought very close to the GPS band (as close as 1558.5 MHz) and the power level is set relatively high. For example, with five contiguous time slots per frame populated, the worst-case measured GPS receiver may attain at least 30 dB of desensitization margin, over the entire ATC service area, even when the ATC is radiating at 1558.5 MHz. With four contiguous time slots per frame populated, an additional 10 dB desensitization margin may be gained for a total of 40 dB for the worst-case measured GPS receiver, even when the ATC is radiating at 1558.5 MHz.

There still may be concern about the potential loss in network capacity (especially in data mode) that may be incurred over the frequency interval where embodiments of Figure 11 are used to underpopulate the frame. Moreover, even though embodiments of Figure 12 can avoid capacity loss by fully loading the carrier, they may do so subject to the constraint of filling up the frame with both low-power and high-power users. Moreover, if forward link carriers are limited to 5 contiguous high power slots per frame, the maximum forward link data rate per carrier that may be aimed at a particular user may become proportionately less.

Therefore, in other embodiments, carriers which are subject to contiguous empty/low power slots are not used for the forward link. Instead, they are used for the return link. Consequently, in some embodiments, at least part of the ATC is configured in reverse frequency mode compared to the SBC in order to allow maximum data rates over the forward link throughout the entire network. On the reverse frequency return link, a radiotelephone may be limited to a maximum of 5 slots per frame, which can be adequate for the return link. Whether the five available time slots per frame, on a reverse frequency return link carrier, are assigned to one radiotelephone or to five different radiotelephones, they can be assigned contiguously in these embodiments. As was described in connection with Figure 12, these five contiguous slots can be assigned to high-power users while the remaining three slots may be used to serve low-power users.

Other embodiments may be based on operating the ATC entirely in reverse frequency mode compared to the SBC. In these embodiments, an ATC transmits over the satellite return link frequencies while radiotelephones respond over the satellite forward link frequencies. If sufficient contiguous spectrum exists to support CDMA technologies, and in particular the emerging Wideband-CDMA 3G standard, the ATC forward link can be based on Wideband-CDMA to increase or maximize data throughput capabilities. Interference with GPS may not be an issue since the ATCs transmit over the satellite return link in these embodiments. Instead, interference may become a concern for the radiotelephones. Based, however, on embodiments of Figures 11-12, the radiotelephones can be configured to transmit GSM since ATC return link rates are expected, in any event, to be lower than those of the forward link. Accordingly, the ATC return link may employ GPRS-based data modes, possibly even EDGE. Thus, return link carriers that fall within a predetermined frequency interval from the GPS band-edge of 1559 MHz, can be under loaded, per embodiments of Figures 11 or 12, to satisfy GPS interference concerns.

Finally, other embodiments may use a partial or total reverse frequency mode and may use CDMA on both forward and return links. In these embodiments, the ATC forward link to the radiotelephones utilizes the frequencies of the satellite return link (1626.5 MHz to 1660.5 MHz) whereas the ATC return link from the radiotelephones uses the frequencies of the satellite forward link (1525 MHz to 1559 MHz). The ATC forward link can be based on an existing or developing CDMA technology (e.g., IS-95, Wideband-CDMA, etc.). The ATC network return link can

also be based on an existing or developing CDMA technology provided that the radiotelephone's output is gated to cease transmissions for approximately 3 msec once every T msec. In some embodiments, T will be greater than or equal to 6 msec.

This gating may not be needed for ATC return link carriers at approximately 1550 MHz or below. This gating can reduce or minimize out-of-band interference (desensitization) effects for GPS receivers in the vicinity of an ATC. To increase the benefit to GPS, the gating between all radiotelephones over an entire ATC service area can be substantially synchronized. Additional benefit to GPS may be derived from system-wide synchronization of gating. The ATCs can instruct all active radiotelephones regarding the gating epoch. All ATCs can be mutually synchronized via GPS.

<u>Terrestrial Reuse of Cellular Satellite Frequency Spectrum in Time-division Duplex Mode</u>

Figure 13 is a schematic diagram of cellular satellite systems and methods according to other embodiments of the present invention, in which a downlink satellite radiotelephone frequency or frequencies is terrestrially reused by an ancillary terrestrial network in a Time-Division Duplex (TDD) mode. In particular, Figure 13 illustrates satellite systems and methods **1300** according to some embodiments of the invention, including an ATC **140** communicating with a radiotelephone **120b** using a downlink carrier frequency $f_D$ in TDD mode.

More specifically, these satellite radiotelephone systems and methods **1300** include a space-based component **110** that is configured to receive wireless communications from radiotelephones, such as the radiotelephone **120a**, in a satellite footprint **130** over an uplink satellite radiotelephone frequency $f_U$ and to transmit wireless communications to the radiotelephones, such as the radiotelephone **120a**, over a downlink satellite radiotelephone frequency $f_D$. An ancillary terrestrial network including at least one ancillary terrestrial component **140** is configured to transmit wireless communications to, and receive wireless communications from, the radiotelephones, such as the radiotelephone **120b**, over the downlink satellite radiotelephone frequency $f_D$ in a time-division duplex mode.

These embodiments of the invention may arise from a recognition that if a downlink satellite radiotelephone frequency $f_D$ is reused terrestrially in time-division duplex mode, bidirectional communications between the ATC **140** and the

radiotelephones **120** may be provided without generating a potential interference path with space-based communications at the satellite **110** and/or the gateway **160**. Stated differently, comparing Figures 4 and 13, the potential interference path **150** of Figure 4 can be reduced and, in some embodiments, eliminated, by using the downlink satellite radiotelephone frequency $f_D$ for time-division duplex communications between the ATC **140** and the radiotelephones **120**.

In other embodiments of the present invention, the ancillary terrestrial network also may be configured to transmit wireless communications to, and receive wireless communications from, the radiotelephones over the uplink satellite radiotelephone frequency $f_U$ in a time-division duplex mode, as was already described in Figure 4. Thus, some embodiments of the present invention can combine Figures 4 and 13 for time-division duplex terrestrial reuse of uplink and downlink satellite radiotelephone frequencies. Other embodiments of the invention may also provided space-based communications with the radiotelephones using the uplink satellite radiotelephone frequency $f_U$ and/or the downlink satellite radiotelephone frequency $f_D$ in a time-division duplex mode.

Various embodiments of TDD modes may be provided according to embodiments of the present invention, similar to the modes which were already described in connection with Figure 4. In some embodiments, the time-division duplex mode includes a frame, for example as was described in Figure 5, including a plurality of slots. At least a first one of the slots is used to transmit wireless communications to the radiotelephones over the downlink satellite radiotelephone frequency $f_D$, and at least one of the slots is used to receive wireless communications from the radiotelephones over the downlink satellite radiotelephone frequency $f_D$.

In still other embodiments, more than one downlink satellite radiotelephone carrier frequency $f_D$ may be used in a TDD mode. Thus, in some embodiments, the entire downlink radiotelephone frequency band may be used to transmit wireless communications to, and receive wireless communications from, the radiotelephones in a time-division duplex mode. A portion of the downlink radiotelephone frequency band also may be used in TDD mode in other embodiments of the present invention.

Moreover, as also was described in connection with Figure 4 above, during data communications or other applications, the downlink may use transmissions at higher rates than the uplink. Hence, other embodiments of the present invention may be configured to enable asymmetrical use of the time slots, to provide a higher

downlink data rate to the radiotelephones. Thus, as was described above in connection with Figure 4, a first number of the slots may be used to transmit wireless communications to the radiotelephones over the downlink satellite radiotelephone frequency, and a second number of the slots may be used to receive wireless communications from the radiotelephones over the downlink satellite radiotelephone frequency, wherein the first number is greater than the second number. In other embodiments, at least a first one of the slots is used to transmit wireless communications to the radiotelephones over the downlink satellite radiotelephone frequency using EDGE modulation and/or protocol, and at least a second one of the slots is used to receive wireless communications from the radiotelephones over the downlink satellite radiotelephone frequency using GPRS modulation and/or protocol. Moreover, in other embodiments, at least a first one of the slots is used to transmit wireless communications to the radiotelephones over the downlink satellite radiotelephone frequency using a first modulation and/or protocol, and at least a second one of the slots is used to receive wireless communications from the radiotelephones over the downlink satellite radiotelephone frequency using a second modulation and/or protocol, wherein the first modulation and/or protocol is more spectrally efficient than the second modulation and/or protocol.

Accordingly, embodiments of the present invention can terrestrially reuse some or all of the downlink satellite radiotelephone frequencies in a time-division duplex mode, to reduce or eliminate interference by the radiotelephones and/or ancillary terrestrial components, with space-based communications at the satellite and/or satellite gateway. An interference reducer may not need to be employed in some embodiments of the present invention, because the frequencies generated by the radiotelephones and/or the ATCs may only be satellite radiotelephone downlink frequencies.

In the drawings and specification, there have been disclosed typical preferred embodiments of the invention and, although specific terms are employed, they are used in a generic and descriptive sense only and not for purposes of limitation, the scope of the invention being set forth in the following claims.
